

Gradual Rt 1.1 -> 1.3 (20-day transition)

Renewal data, $I_0 = 2000$, $T = 100$, $n_{sim} = 100$, correct serial interval (mean = 7.5, sd = 3.4). Each estimator gets data from its own observation model: EpiEstim and EpiFilter Poisson, EpiLPS negative binomial ($\rho = 20$), same seed. Left column: the representative epidemic of each data set (Poisson #33, negative binomial #46). Band = 95% credible interval; dashed = 2.5–97.5 percentile spread of the point estimate across simulations. EpiEstim: 1-day window. EpiFilter: smoother, $\eta = 0.1$, from day 8. EpiLPS: $K = 30$, fitted to days 8–100; MALA 5000 iterations, 2000 burn-in.

Gradual Rt 1.1 -> 1.3 (20-day transition): per-day comparison

Dotted lines mark the transition (days 50–69). Axis ranges are set from days 25–100 (view only; metrics start at day 8). n_sim = 100; with few replicates coverage moves in coarse steps.
